Updating the Beers Criteria for Potentially Inappropriate Medication Use in Older Adults

Results of a US Consensus Panel of Experts

Donna M. Peck, PhD, RN; James W. Cooper, PhD, RPh; William E. Wade, PharmD, FASHP, FCCP; Jennifer L. Walker, PhD; J. Scott Studdert, MA; Mark A. Scott, MA*

Arch Intern Med. 2003;163:2716-2724

Table 1. 2002 Criteria for Potentially Inappropriate Medication Use in Older Adults. Independent of Diagnosis or Condition

Drug	Comments
Propoxyphene (Darvocet) and combination products (Gesic with ASA, Vicoprofen, and Darvocet-N)	Offers few analgesic advantages over acetaminophen, yet has the adverse effects of other narcotics drugs. CV risk associated with antiinflammatory dosage. Very strong prokinetic for recent CNS adverse effects.
Pentazocine (Talwin)	Harmful analgesic that causes more CNS adverse effects, including nephrotoxic and hepatotoxic, more commonly than other narcotic drugs. Additionally, it is a mixed agonist and antagonist.
Tenoxicam (Tygel)	Most of the least effective antiarthritic drugs, yet it can cause orthopedic adverse effects.
Muscle relaxants and anticonvulsants: metocarbamol (Robax), carisoprodol (Soma), clonazepam (Klonopin), meprobamate (Miltown), cyclobenzaprine (Flexeril), and carbamazepine (Tegretol). Do not consider the extended-release Oxytropin XL.	Most muscle relaxants and anticonvulsants drugs are poorly tolerated by elderly patients, since these cause anticholinergic adverse effects, sedation, and incontinence. Additionally, their effectiveness at doses tolerated by elderly patients is questionable.
Phenothiazine (Promethazine)	This imidazoline receptor, has an extremely long half-life in elderly patients (several days), inducing prolonged sedation and increasing the incidence of falls and fractures. Moderate- or short-acting benzodiazepines are preferred.
Antihistamines (Cetirizine, desloratadine, fexofenadine, loratadine, and cetirizine-dextromethorphan, Zyrtec)	Because of its strong anticholinergic and sedating properties, diphenhydramine is rarely the antihistamine of choice for elderly patients.
Anticholinergics (Mirtazapine and Sibutramine)	Because of its strong anticholinergic and sedating properties, diphenhydramine is rarely the antihistamine of choice for elderly patients.

Oral short-acting benzodiazepines: doses greater than lorazepam (Ativan), 2 mg; oxazepam (Klonopin), 60 mg; alprazolam (Xanax), 2 mg; temazepam (Restoril), 15 mg; and triazolam (Halcion), 0.25 mg	Need to be withdrawn slowly. Because of increased sensitivity to benzodiazepines in elderly patients, smaller doses may be effective as well as safer. Total daily doses should exceed the suggested maximums.
Long-acting benzodiazepines: clorazepate (Tranxene), chlordiazepoxide and diazepam (Librium), clorazepate, chlordiazepoxide (Librax), Xanax (Valium), clorazepate (Tranquillan), clorazepate (Tranquilon), and clorazepate (Tranxene)	These drugs have a long half-life in elderly patients (often several days), inducing prolonged sedation and increasing the risk of falls and fractures. Short- and intermediate-acting benzodiazepines are preferred to a benzodiazepine (triazolam).
Oral antiarrhythmic drugs: this is the most potent negative inotropic agent that may induce heart failure in elderly patients. It is also strong antiholistic. Other antiarrhythmic drugs should be used.	Decreased renal clearance may lead to increased risk of toxic effects.
Digoxin (Lanoxin) (should not exceed >0.125 mg/d except when managing atrial fibrillation)	May cause orthostatic hypotension.
Short-acting diuretics (Furosemide). Do not consider the	

Short-acting diuretics (Furosemide). Do not consider the long-acting diuretics (which has better proprano than the short-acting in older adults) except with patients with artificial heart valves.	May cause orthostatic hypotension.
Metformin (Glucophage) and methyldopa hydrochloride (Aldomet)	May induce depression, impotence, sedation, and orthostatic hypotension. It has a prolonged half-life in elderly patients and could cause prolonged hypoglycemia. Additionally, it is the only oral hypoglycemic agent that is OTC (OTC 500mg).
Clozapine (Clozaril) and clorazepate (Tranxene)	Clorazepate drugs are highly anticholinergic and have untoward side effects. These drugs should be avoided especially for elderly patients.
Antihistamines and anticholinergics: diphenhydramine (Sominex), doxylamine (Unisom), chlorpheniramine (Chlor-Trimeton), chlorpheniramine (Chlor-Trimeton), hydroxyzine (Vistaril and Razipac), codeine (Percodan), acetaminophen (Tylenol), tramadol, and diphenhydramine (Hycetin).	All anticholinergics and many antihistamines may have potent anticholinergic properties. Nonanticholinergic antihistamines are preferred in elderly patients who evidence allergic reactions.
Dihydroergotamine (Dihydro)	May cause constipation and sedation. Should not be used as a hypnotic, and when used to treat emergency allergic reactions, it should be used in the smallest possible doses.
Ergot derivatives (Diadermine) and cyclandelate (Cinnarizine) (Tarsicard) Tarsicard sulfate >25 mg/d	Do not exceed 100 mg/d since this does not dramatically increase the amount absorbed but greatly increases the times of constipation.
All tricyclics (except phenothiazine) except when used to control seizures	Anticholinergics and some more adverse effects than most antihistamine drugs in elderly patients.

Drug	Comments
Meprobamate (Danzac)	Not an effective oral analgesic. In chronic nonmigraine use, may cause confusion and has many disadvantages to other narcotic drugs. Has been shown to be no better than aspirin at preventing cramping and may be considerably more toxic. Other, more effective alternatives exist.
Ketorolac (Toradol)	Intermediate and long-term use should be avoided in older persons, since a significant number have asymptomatic GI perforations, vasodilatation, tachycardia, and respiratory depression. These drugs have potential for causing dependence, hypertension, angina, and respiratory depression.
Long-term use of NSA-drugs: non-COX inhibitors include ibuprofen (Advil, Motrin, Aleve), and naproxen (Naprosyn, Anaprox, and Aleve, Naprosyn (Deltrex), and piroxicam (Feldene). They include (Toradol).	High half-life of drug and risk of producing excessive CNS stimulation, sleep disturbances, and excessive nystagmus. Other alternatives exist. May exacerbate heart dysfunction.
Amphetamine (Dexedrine)	Associated with QT interval prolongation and risk of precipitating torsades de pointes. Lack of efficacy in older adults.

Phenothiazine (Benzodiazepines)	POTENTIAL DANGER IN OLDER ADULTS: Causes more sedation and anticholinergic adverse effects than older alternatives. May cause orthostatic hypotension. Older alternatives exist. May cause orthostatic hypotension.
Clozapine (Clozaril)	Lack of efficacy.
Cyclandelate (Cyclobenzaprine)	Potential for renal impairment. Some alternatives available.
Imipramine (Norpramin)	Potential for hypertension, dry mouth, and urinary problems.
Desipramine (Norprilin)	Potential for psychostimulation and cardiac problems.
Methyldopa (Aldomet, Vireliz, and Resintec)	Greater potential for CNS and antihypertensive adverse effects.
Thioridazine (Mellaril)	CNS and sedoliberinadilant adverse effects.
Mianserin (Savella)	Potential for hypertension and constipation.
Short acting tricyclines (Prozadine and Asendin)	Potential for hypertension and constipation.
Clorazepate (Tranxene)	Potential for orthostatic hypotension and CNS adverse effects.
Mineral oil	Potential for aspiration and adverse effects. Other alternatives available.
Clozepine (Paxipam)	CNS adverse effects including confusion.
Fluoxetine (Prozac)	Potential for hypertension and fainting episodes. Other alternatives available.
Doxepin (Admet)	Concern about cardiac effects. Other alternatives available.
Amitriptyline (including mianserin, imipramine hydrochloride and amoxapine)	CNS stimulant adverse effects.
Ethosuximide (Zarontin)	Evidence of the carcinogenic threat and endometrial cancer potential of these agents and lack of cardioprotective effect in older women.

Agitation

- Parfois possibilité de contact et examen clinique, maintient de la relation avec contact oral
- Dans les cas extrêmes : Contention physique
- Sédation médicamenteuse
 - La voie orale est souvent suffisante
 - Injectable si nécessaire
 - Par voie IM car pratique (mais pas plus rapide!)

Agitation

Atypical antipsychotic drugs and risk of ischaemic stroke: population based retrospective cohort study

Sudeep S Gill, Pratik A Kocher, Nathan Hermann, Philip E Lee, Kathy Sikora, Nadia Gouaji, Sharmistha J Narmand, Jerry H Gorstein, Connie Marras, Walter P Wadleigh, Mohammad Mamdani

Atypical antipsychotic drugs and risk of ischaemic stroke:
population based retrospective cohort study
Sudeep S Gill,

- **Objective** To compare the incidence of admissions to hospital for stroke among older adults with dementia receiving atypical or typical antipsychotics.

Atypical antipsychotic drugs and risk of ischaemic stroke:
population based retrospective cohort study
Sudeep S Gill,

- **Patients** 32 710 older adults (≥ 65 years) with dementia (17 845 dispensed an atypical antipsychotic and 14 865 dispensed a typical antipsychotic).

Design Population based retrospective cohort study.
Setting Ontario, Canada.

**Atypical antipsychotic drugs and risk of ischaemic stroke:
population based retrospective cohort study**
Sudeep S Gill,

- Main outcome measures** Admission to hospital with the most responsible diagnosis (single most important condition responsible for the patient's admission) of ischaemic stroke. Observation of patients until they were either admitted to hospital with ischaemic stroke, stopped taking antipsychotics, died, or the study ended

**Atypical antipsychotic drugs and risk of ischaemic stroke:
population based retrospective cohort study**
Sudeep S Gill,

- Results** After adjustment for potential confounders, participants receiving atypical antipsychotics showed **no significant increase** in risk of ischaemic stroke compared with those receiving typical antipsychotics (adjusted hazard ratio 1.01, 95% confidence interval 0.81 to 1.26). This finding was consistent in a series of subgroup analyses, including ones of individual atypical antipsychotic drugs (risperidone, olanzapine, and quetiapine) and selected subpopulations of the main cohorts.

**Atypical antipsychotic drugs and risk of ischaemic stroke:
population based retrospective cohort study**
Sudeep S Gill,

- Conclusion** Older adults with dementia who take atypical antipsychotics have a similar risk of ischaemic stroke to those taking typical antipsychotics.

Characteristics	Atypical antipsychotics cohort (n=17 845)	Typical antipsychotics cohort (n=14 865)
Mean (SD) age (years)	82.5 (7.3)	82.7 (7.4)
Men	6431 (36.0)	5727 (38.5)
Long term care	9495 (47.5)	7682 (51.7)
Low income	6588 (37.5)	5807 (39.1)
Urban residence	2807 (15.7)	2673 (18.0)
Mean (SD) frequency of medical contact (days)*	33.3 (25.4)	34.3 (26.8)
Year of entry to cohort:		
1997	598 (3.4)	5452 (36.7)
1998	1688 (8.0)	4570 (30.7)
1999	3896 (20.7)	2880 (18.0)
2000	5589 (31.3)	1921 (9.9)
2001	6374 (35.7)	842 (5.7)
Chronic users†	13792 (77.3)	9929 (66.8)

Table 2 Event rates and hazard ratios for older adults with dementia receiving atypical or typical antipsychotics

Main analysis (full cohorts)	Atypical antipsychotic cohort (n=17 048)	Typical antipsychotic cohort (n=14 868)
No (%) of new admissions for ischaemic stroke	264 (1.6)	227 (1.5)
Mean (SD) duration of follow up (days)	227.2 (264.0)	209.1 (306.4)
Crude event rate (No of events per 1000 person years)*	25.5	22.3
Unadjusted hazard ratio (95% CI)†	1.00 (0.89 to 1.27)	1.00
Adjusted hazard ratio (95% CI)‡	1.01 (0.81 to 1.26)	1.00

*(No of events)/(No of days per 365 days)×1000.
†Adjusted for age; sex; low income status; residence in long term care; frequency of medical contact; year of entry to cohort; history of stroke in past five years; history of atrial fibrillation; hypertension; diabetic mellitus; acute myocardial infarction in past three months; congestive heart failure; number of distinct drugs; chronic use (>7 consecutive prescriptions) of antipsychotics; and baseline use of warfarin; antibiotics; drugs; antihypertensive drugs; angiotensin converting enzyme inhibitors; lipid lowering drugs; oral diabetic drugs; and hormone replacement therapy.

What is already known on this topic

Atypical antipsychotics are commonly used to manage behavioural and psychological symptoms of dementia (BPSD).

Recent evidence from clinical trials suggests an association between atypical antipsychotic use and cardiovascular events (including stroke) among older adults with BPSD.

These data prompted the UK Committee on Safety of Medicines to recommend against the prescribing of atypical antipsychotics for patients with BPSD.

The choice of atypical or typical antipsychotics to manage BPSD should not be based on concerns about the risk of stroke.

Findings were consistent for a series of subgroup analyses including ones for patients at high baseline risk of stroke.

The choice of atypical or typical antipsychotics to manage BPSD should not be based on concerns about the risk of stroke.

Risk of myocardial infarction in patients taking cyclo-oxygenase-2 inhibitors or conventional non-steroidal anti-inflammatory drugs: population based nested case-control analysis

Jois Hippocrate, Case Control

BMJ VOLUME 330 11 JUNE 2005 [bmj.com](#)

**9218 cases with a first ever diagnosis of myocardial infarction during the four year study period
86 349 controls matched for age, calendar year, sex, and practice.**

A significantly increased risk of myocardial infarction was associated with current use of rofecoxib (adjusted odds ratio 1.32) compared with no use within the previous three years; with current use of diclofenac (1.55); and with current use of ibuprofen (1.24).

What is already known on this topic

The VIGOR study found that rofecoxib was associated with an increased risk of myocardial infarction compared with naproxen.

Uncertainty exists as to whether this reflected a true increase or an apparent increase due to a cardioprotective effect of naproxen.

Rofecoxib has been withdrawn, but uncertainty persists about the cardiovascular safety of the other selective cyclooxygenase-2 inhibitors (NSAIDs).

What this study adds

Rofecoxib, diclofenac, and ibuprofen were associated with a higher risk of myocardial infarction; no evidence of a cardioprotective effect for naproxen was found.

The increased risk with rofecoxib in the VIGOR study was genuine; the toxicity of conventional NSAIDs and newer selective NSAIDs is also of concern.

No clinically important interactions occurred between any NSAID and either aspirin or coronary heart disease.

The Risk for Myocardial Infarction with Cyclooxygenase-2 Inhibitors: A Population Study of Elderly Adults

Laura E. Johnson, Michael R. Glynn, David M. Berlowitz, Bill Stricklin, and Bill Stricklin, MD

Ann Intern Med. 2005;142:401-409.

Conclusions: These results provide evidence of an increased risk for acute MI in current users of rofecoxib among elderly persons with no history of MI. This risk appears greater at higher doses. Aspirin use mitigates the risk associated with low-dose but not high-dose rofecoxib. There was no evidence of an increased risk with the other NSAIDs.

Hyperkalaemia and impaired renal function in patients taking spironolactone for congestive heart failure: retrospective study

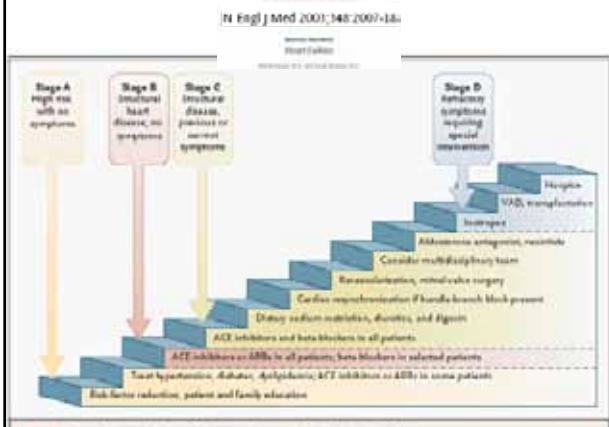

Medical Research and Education, Northumbria, UK; BHF Research, Newcastle

Bmf 2003;327:1191-2

Comment

Taking spironolactone for congestive heart failure is associated with considerably more frequent side effects than previously thought. Age, lower LVEF, and higher NYHAFC are predictors of hyperkalaemia and azotaemia.

A Risk Score for Predicting Stroke or Death In Individuals With New-Onset Atrial Fibrillation in the Community The Framingham Heart Study

Thomas J. Wang, MD
Joseph M. Massaro, PhD
David E. Levy, MD
Ramaswamy S. Vasan, MD
Philip A. Wolf, MD
Ralph V. Di Stefano, PhD
Marvin G. Larson, PhD
William B. Kannel, MD
Enrique J. Benjamin, MD, ScM

ATRIAL FIBRILLATION (AF) IS THE MOST COMMON CARDIAC RHYTHM DISORDERS, AFFECTING MORE THAN 2 MILLION IN

OBJECTIVE: Prior risk stratification schemes for atrial fibrillation (AF) have been based on randomized trial cohorts or Medicare administrative databases. We excluded patients with established AF, and have focused on stroke as the principal outcome.

OBJECTIVE: To derive risk scores for stroke alone and stroke/death in community-based individuals with new-onset AF.

Design, Setting, and Participants: Prospective, community-based, observational cohort in Framingham, Mass. We assessed 400 participants with new-onset AF, 200 of whom were not treated with oral anticoagulation. Participants were followed up until death, stroke, or hospitalization for stroke or death, or through December 2003, whichever occurred during follow-up. Death rates were assessed in three risk categories, as defined by the risk score and a previously published risk scheme.

Main Outcomes Measures:

Results: During a mean follow-up of 6.0 years free of previous stroke, stroke alone was reported in 23 individuals and stroke/death in 194 participants. Risk scores for stroke and death that excluded the following risk variables, advancing age, female sex, increasing systolic blood pressure, prior stroke or transient ischemic attack, and smoking, were developed.

Figure 1. Risques prédictifs d'AVC à 5 ans.

A COMPARISON OF RATE CONTROL AND RHYTHM CONTROL IN PATIENTS WITH ATRIAL FIBRILLATION

THE ATRIAL FIBRILLATION FOLLOW-UP INVESTIGATION OF RHYTHM MANAGEMENT (AFFIRM) INVESTIGATORS*

None of the presumed benefits of rhythm control noted above were confirmed in this study. The implication is that rate control should be considered a primary approach to therapy and that rhythm control, if used, may be abandoned early if it is not fully satisfactory. Our data also suggest that continuous anticoagulation is warranted in all patients with atrial fibrillation and risk factors for stroke, even when sinus rhythm appears to be restored and maintained.

N Engl J Med, Vol. 347, No. 23 • December 5, 2002

Oral Cyanocobalamin Supplementation in Older People With Vitamin B₁₂ Deficiency

A Disease-Finding Trial

James J. P. M. Eijken, MSc; Lisette C. P. G. M. de Groot, PhD; Robert Clarke, MD; Jiri Schenck, MD; Peter M. Uylstra, MSc; William H. J. Horstink, MD, PhD; Willem A. van Maanen, PhD

Arch Intern Med. 2005;165:1167-1172

Daily doses of 647 to 1032 µg of cyanocobalamin

Conclusion: The lowest dose of oral cyanocobalamin required to normalize mild vitamin B₁₂ deficiency is more than 200 times greater than the recommended dietary allowance, which is approximately 3 µg daily.

Vitamin E and Donepezil for the Treatment of Mild Cognitive Impairment

Ronald C. Petersen, M.D., Ronald G. Thomas, M.D., Michael Grundman, M.D., M.P.H.,

N Engl J Med 2005;352:

CONCLUSIONS

Vitamin E had no benefit in patients with mild cognitive impairment. Although after three years, the rate of progression to Alzheimer's disease was not lower among patients treated with donepezil than among those given placebo, donepezil therapy was associated with a lower rate of progression to Alzheimer's disease during the first 12 months of treatment.

Role of multivitamins and mineral supplements in preventing infections in elderly people: systematic review and meta-analysis of randomised controlled trials

Arie F. Knijnenburg, Alexander J. Smit

BMJ 2005;330:871-1, originally published online 31 Mar 2005:

Conclusion The evidence for routine use of multivitamin and mineral supplements to reduce infections in elderly people is weak and conflicting. Study results are heterogeneous, and this is partially confounded by outcome measure.

Routine oral nutritional supplementation for stroke patients in hospital (FOOD): a multicentre randomised controlled trial

Lancet 2005; 365:755-61

The FOOD Trial Collaboration*

Interpretation We could not confirm the anticipated 4% absolute benefit for death or poor outcome from routine oral nutritional supplements for mostly well nourished stroke patients in hospital. Our results would be compatible with a 1% or 2% absolute benefit or harm from oral supplements. These results do not support a policy of routine oral supplementation after stroke.

Effect of timing and method of enteral tube feeding for dysphagic stroke patients (FOOD): a multicentre randomised controlled trial

* The FOOD Trial Collaboration*

Interpretation Early enteral feeding might reduce case fatality, but at the expense of increasing the proportion surviving with poor outcome. Our data do not support a policy of early initiation of ENG feeding in dysphagic stroke patients.

Effect of timing and method of enteral tube feeding for dysphagic stroke patients (FOOD): a multicentre randomised controlled trial

Albumin, Length of Stay, and Proton Pump Inhibitors: Key Factors in *Clostridium difficile*-Associated Disease in Nursing Home Patients

Karen Ibrahim J. Al-Tarabieh, M.D., Ali Hassanien, M.D., Linda Walford, M.D., and Henry Fischberg, M.D.
(J Am Med Dir Assoc 2005; 6: 105-108)

Objectives: To identify risk factors for *Clostridium difficile*-associated disease (CDAD) in nursing home patients.

The third significant risk factor was the use of proton pump inhibitors, 60% versus 32%, respectively (2.4.137; df 1; P .05). Levofloxacin was the most frequently prescribed antibiotic (37%).

A Prescribing Cascade Involving Cholinesterase Inhibitors and Anticholinergic Drugs

Fadi F. Ghali, MD, MSc, FRCPC; Mohammad Hamedan, PharmD, MSc, HFPH; Cory Higgins, MD, FRCPC; David L. Isenman, PhD; Jason E. Frenchell, PhD; Alexander Kopp, PhD; Kenneth J. Shulman, MD, MM, FRCPC; Stephen E. Lee, MD, FRCR, FCACR; Michael A. Banerji, MHS, MPH, FRCR

Arch Intern Med 2005;165:808-813

Methods: A population-based retrospective cohort study was carried out in Ontario, Canada. Participants included 44 804 older adults with dementia (20 491 were dispensed a cholinesterase inhibitor and 24 303 were not), enrolled between June 1, 1999, and March 31, 2002. Sub-

- Adults with dementia who were dispensed cholinesterase inhibitors had an increased risk of subsequently receiving an anticholinergic drug (4.5% vs 3.1%; $P=0.001$; adjusted hazard ratio, 1.55; 95% confidence interval, 1.39- 1.72), relative to those not receiving cholinesterase inhibitors.
